Copy No. 4 of 4 copies

## INTRODUCTION

Airborne and impact sound transmission measurements were performed on a floor assembly with 6 mm ceramic tiles, 13 mm cement board, 8 mm Duraflex and a 146 mm thick concrete slab. For report purposes, this specimen is identified Specimen B3135-4. A complete description of the floor assembly is outlined in this report (see Specimen Description Section).

## FACILITIES AND EQUIPMENT

The acoustics floor test facility comprises two reverberation rooms with a moveable test frame between the two rooms. Both rooms have a volume of 175 $m^3$.

Measurements are controlled by a desktop PC-type computer interfaced to a Norwegian Electronics type 830 real time analyser. Each room has a calibrated Bruel & Kjaer condenser microphone cartridge-type 4166 that is moved under computer control to nine positions used for the acoustical measurements. Each room has four loudspeakers driven by separate amplifiers and noise sources. To increase the randomness of the sound field, there are also fixed diffusing panels in each room.

## TEST PROCEDURE

### *Airborne Sound Transmission Loss*

Airborne sound transmission measurements were conducted in accordance with the requirements of ASTM E90-90, "Standard Method for Laboratory Measurement of Airborne Sound Transmission Loss of Building Partitions", and of ISO 140/III 1978(E), "Laboratory Measurement of Airborne Sound Insulation of Building Elements".

The Sound Transmission Class (STC) was determined in accordance with ASTM E413-87, "Classification for Rating Sound Insulation". The Weighted Sound Reduction Index ($R_w$) was determined in accordance with ISO 717, "Rating of Sound Insulation in Buildings and of Building Elements, Part 1: Airborne Sound Insulation in Buildings and of Interior Building Elements".

One-third octave band sound pressure levels were measured for 32 seconds at each microphone position and then averaged to get the average sound pressure level in the room. Five sound decays were averaged to get the reverberation time at each microphone position in the receiving room. These times were averaged to get the spatial average reverberation times for the room.

The space average sound pressure levels of both the source and receiving rooms and the spatial average reverberation times of the receiving room were used to calculate sound transmission loss values.

Airborne sound transmission loss tests were performed in the forward (receiving room is the lower room) and reverse (receiving room is the upper room) directions. Results presented in this report are the average of the tests in these two directions.

A complete description of the test procedure, information on the flanking limit of the facility and reference specimen test results are available on request.

The measured temperature and relative humidity in the upper chamber during testing was 27.7°C and 38.8%, respectively. The measured temperature and relative humidity in the lower chamber during testing 25.6°C and 49.7%, respectively.

## TEST PROCEDURE

### *Impact Sound Transmission*

Impact sound transmission measurements were made in accordance with ASTM E492-90, "Standard Test Method for Laboratory Measurement of Impact Sound Transmission Through Floor-Ceiling Assemblies Using the Tapping Machine". This test used the standard tapping machine and the prescribed four impact positions on the floor. The Impact Insulation Class (IIC) was determined in accordance with ASTM E989-89, "Standard Classification for Determination of Impact Insulation Class (IIC)".

These measurements are also in accordance with ISO 140-6, "Laboratory Measurements of Impact Sound Insulation of Floors", except that the tapping machine positions are not randomly selected. This difference is believed to be insignificant. The Weighted Normalized Impact Sound Pressure Level ($L_{n,w}$) was determined in accordance with ISO 717, "Rating of Sound Insulation in Buildings and of Building Elements - Part 2: Impact Sound Insulation".

One-third octave band sound pressure levels were measured for 32 seconds at each microphone position in the receiving room and then averaged to get the average sound pressure level in the room. Five sound decays were averaged to get the reverberation time at each microphone

position in the receiving room. These times were averaged to get the spatial average reverberation times for the room.

The space average sound pressure levels and the spatial average reverberation times of the receiving room were used to calculate impact transmission values. For impact sound transmission, the lower room is the receiving room.

In addition to the requirements of this contract, calculations were made according to ISO 717, Rating of sound insulation in buildings and building elements. - Part 2 : Impact sound insulation. These calculations are summarized in the Additional Calculations Section.

A complete description of the test procedure is available on request.

**MOUNTING OF SPECIMEN**

The test specimen was mounted in the IRC acoustical floor test opening which measures 4.70 m x 3.78 m. The area used for the calculations of impact transmission and airborne sound transmission loss was 17.85 $m^2$.

**SPECIMEN DESCRIPTION**

Construction on the floor assembly began on 25-Jun-99. The airborne sound transmission loss tests were performed on 30-Jun-99. The floor assembly comprised the following elements, listed from top to bottom.

Table 1: Element breakdown of Specimen B3135-4.

| Element | Surface weight ($kg/m^2$) | Mass (kg) |
|---|---|---|
| 6 mm ceramic tiles | 15.5 | 326.1 |
| 13 mm cement board | 13.4 | 271.2 |
| 8 mm Duracoustic | 3.0 | 60.0 |
| 146 mm thick concrete slab | 356.3 | 7029.5 |
| **TOTAL** | | **7686.8** |

Total thickness: 173.0 mm

The 146 mm concrete reference slab, provided by NRC, was installed in the floor test frame. Pieces of 8 mm thick shredded rubber material, identified by the client as

"Duraflex"

"Duracoustic", were installed directly on top of the concrete slab. The "Duracoustic" was installed with the rubber side against the concrete slab. 13 mm thick pieces of Westroc Panaroc cement board with Edgetech were installed on top of the "Duracoustic" The joists of the cement board were taped and cemented as per installation instructions. 6 mm thick ceramic tiles were installed on top of the cement board according to the manufacturer's instructions.

## RESULTS

Results of the airborne sound transmission loss measurements of Specimen B3135-4 are given in Table 2 and Figure 1. Results of the impact sound transmission measurements of this floor construction are given in Table 3 and Figure 2.

Certain values in the tables are marked. The values marked "*" indicate that the measured background level was less than 5 dB below the combined receiving room level and background level. The reported values provide an estimate of the lower limit of airborne sound transmission loss or impact transmission. These values do not limit the single number ratings. The values marked "c" indicate that the measured background level was between 5 dB and 10 dB below the combined receiving room level and background level. The reported values have been corrected according to the procedure outlined in ASTM E90-97 or ASTM E492-90.

[1] Acoustical measurement in rooms is a sampling process and as such has associated with it a degree of uncertainty. By correctly performing a number of measurements, the uncertainties can be reduced and upper and lower limits assigned to the probable error in the measurement. These limits are called confidence limits. Thus where a quantity (Q) has associated with it a confidence limit ±C, then one can say with 95% confidence that the true quantity is in the interval Q - C to Q + C.

## ADDITIONAL CALCULATIONS

In addition to the requirements of this contract, calculations were made according to ISO 717 Rating of sound insulation in buildings and building elements. - Part 2: Impact sound insulation.

The calculations for evaluating the weighted impact sound improvement index of floor coverings are shown in the tables below.

The ISO 717 impact sound rating is called the weighted normalized impact sound pressure level and is denoted $L_{n,w}$. The rating curve is identical to that used in calculating the ASTM IIC rating. The sole difference in the fitting procedure is that the ISO standard allows unfavorable deviations to exceed 8 dB; the ASTM E989 standard does not. When this 8 dB limitation is not invoked, the two ratings are related by the equation

$$IIC = 110 - L_{n,w}$$

The ISO reference slab has an IIC rating of 28 and $L_{n,w} = 78$ dB.

Table 4 shows the reduction in normalized impact sound pressure level relative to the 146 mm concrete slab for the specimen tested. Following the procedures in ISO 717, these differences were added to the impact sound levels for the idealized reference floor in that standard. The levels for the reference floor and the estimated levels for the specimen are shown in Table 5. $L_{n,w,r}$ in that table is the estimated value of normalized impact sound pressure level for the tested toppings on the reference ISO slab. $\Delta L_w$ is the improvement in weighted normalized impact sound pressure level. This number is not equal to the improvement in IIC because the 8 dB rule was applied when calculating the IIC for the bare 146 mm thick IRC concrete slab.

Table 4: Reduction in normalized impact sound pressure level relative to the 146 mm concrete slab.

## NOTES ON THE SIGNIFICANCE OF TEST RESULTS

### *Sound Transmission Class And Weighted Sound Reduction Index*

The Sound Transmission Class (STC) and Weighted Sound Reduction Index ($R_w$) are single-figure rating schemes intended to rate the acoustical performance of a partition element under typical conditions involving office or dwelling separation. The higher the value of either rating, the better the floor performance. Thus, the rating is intended to correlate with subjective impressions of the sound insulation provided against the sounds of speech, radio, television, music, office machines and similar sources of noise characteristic of offices and dwellings. In applications involving noise spectra that differ markedly from those referred to above (for example, heavy machinery, power transformers, aircraft noise, motor vehicle noise), the STC and $R_w$ are of limited use. Generally, in such applications it is desirable to consider explicitly the noise spectra and the insulation requirements.

### *Impact Insulation Class And Weighted Normalized Impact Sound Pressure Level*

The Impact Insulation Class (IIC) and the Weighted Normalized Impact Sound Pressure Level ($L_{n,w}$) are single-figure rating schemes intended to rate the effectiveness of floor-ceiling assemblies at preventing the transmission of impact sound from the standard tapping machine. The higher the value of the rating, the better the floor performance.
